# Amazon\_Movies\_and\_TV\_Ratings

## **DESCRIPTION**

The dataset provided contains movie reviews given by Amazon customers. Reviews were given between May 1996 and July 2014.

# **Data Dictionary**

**UserID** – 4848 customers who provided a rating for each movie

**Movie 1 to Movie 206** – 206 movies for which ratings are provided by 4848 distinct users

### **Data Considerations**

- All the users have not watched all the movies and therefore, all movies are not rated. These missing values are represented by NA.
- Ratings are on a scale of -1 to 10 where -1 is the least rating and 10 is the best.

# **Import Important librarys**

```
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
%matplotlib inline
```

```
import warnings
warnings.filterwarnings("ignore")

# Read Data in the data frame
df=pd.read_csv('Amazon - Movies and TV Ratings.csv')

# Show data frame
df
```

# pandas.DataFrame.T() function

**pandas.DataFrame.T** property is used to transpose index and columns of the data frame.

The property T is somehow related to method transpose().

The main function of this property is to create a reflection of the data frame overs the main diagonal by making rows as columns and vice versa.

```
df.describe().T
```

### **Recommendation Model:**

1.0

Movie68

Some of the movies hadn't been watched and therefore, are not rated by the users. Netflix would like to take this as an opportunity and build a machine learning recommendation algorithm which provides the ratings for each of the users.

- Divide the data into training and test data
- Build a recommendation model on training data
- Make predictions on the test data

# Import Recommendation Model related Librarys

```
from surprise import Reader
from surprise import accuracy
from surprise import Dataset
from surprise.model_selection import train_test_split
from surprise import SVD
from surprise.model_selection import cross_validate
from surprise.model_selection import GridSearchCV
```

**melt()** function is useful to message a DataFrame into a format where one or more columns are identifier variables, while all other columns, considered measured variables, are unpivoted to the row axis, leaving just two non-identifier columns, variable and value.

# df.head(2)

```

info
<surprise.dataset.DatasetAutoFolds at 0x249f45d4eb0>
trainset,testset=train_test_split(info,test_size=0.20)
```

**Singular Value Decomposition (SVD)** is one of the widely used methods for dimensionality reduction. SVD decomposes a matrix into three other matrices.

If we see matrices as something that causes a linear transformation in the space then with Singular Value Decomposition we decompose a single transformation in three movements.

```
#Usingn svd
svd = SVD()
svd.fit(trainset)
<surprise.prediction_algorithms.matrix_factorization.SVD at
0x249f45d4760>
predect = svd.test(testset)
accuracy.rmse(predect)
RMSE: 0.2790
```

0.2789579259730664

**RMSE** is an acronym for **Root Mean Square Error**, which is the square root of value obtained from Mean Square Error function.

Using RMSE, we can easily plot a difference between the estimated and actual values of a parameter of the model.

$$RMSE = \sqrt{\frac{\sum_{i=1}^{N} (Predicted_i - Actual_i)^2}{N}}$$

accuracy.mae(predect)

MAE: 0.0410

RMSE (testset)

0.04097044673118672

**Mean Absolute Error (MAE)** is calculated by taking the summation of the absolute difference between the actual and calculated values of each observation over the entire array and then dividing the sum obtained by the number of observations in the array.

```
(1/n)*\Sigma|yi-xi| cross\_validate(svd, info, measures = ['RMSE', 'MAE'], cv = 3, verbose = True) Evaluating RMSE, MAE of algorithm SVD on 3 split(s). Fold 1 Fold 2 Fold 3 Mean Std
